

Revisions on Minutes

--- Add description for the near landmarks or other details to easily locate the incidents ---

A map pin or address is not always enough to find the place. Let the reporter also write things like "near the church" or "beside the school."

Apply: Add a "Landmark / Additional Details" (pero as optional lang pod) text field to the incident report form and the reports table in the database. Show it in the incident details page, the responder view, and the map popup.

SUBMIT EMERGENCY REPORT

False reporting is punishable by law

--- NIR: Identify the congressional district, then the city/town, then that is where the report goes ---

NIR is Negros Island Region. The report should be sorted by location: first choose the congressional district, then the city or town. The report then goes to that area's office. ("Dira masulod ang report")

1. Backend (this is where the sorting happens now)

When the report arrives, the system finds the city/town from the coordinates, then finds the congressional district of that city/town. It can do this by checking which city/town boundary the point falls inside. You need boundary data for this, such as a GeoJSON file of the NIR city and town boundaries. PostGIS in your PostgreSQL can do the check. Then save the district and city/town on the report automatically.

2. Database

Same as before: the reports table still gets a district field and a city/town field. They are just filled in by the system, not by the user.

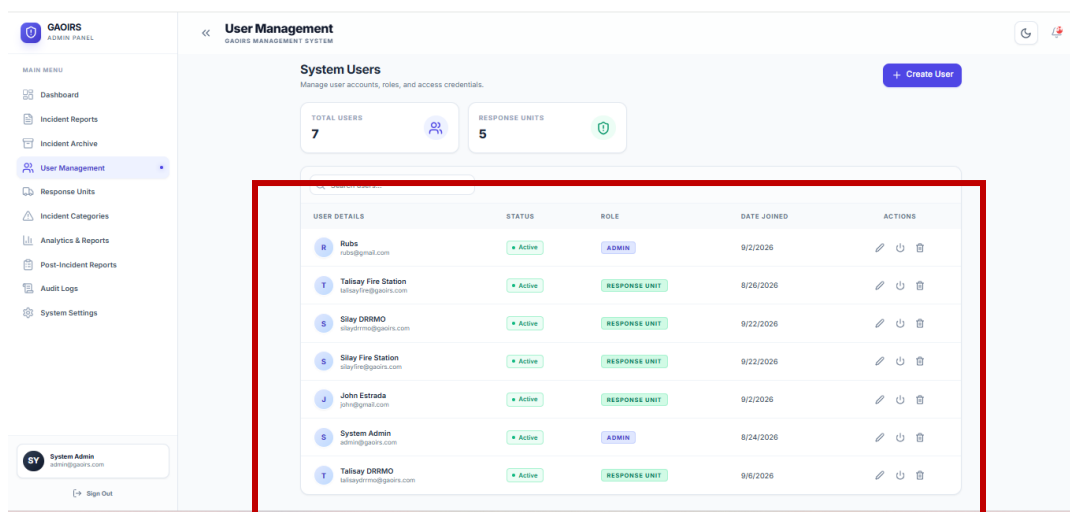

3. Admin/responder dashboard

No change. Reports are still filtered by the user's district and city/town, so the right responders see the report.

--- User Management: Maobra by congressional ---

User accounts should be organized by congressional district. An admin or responder only handles reports from their own district.

Apply: The users table (add a district field), user roles and permissions, and filters on the dashboard Reports and reports list.

--- Put Analytics--- (Check ni oh kung na apply man gid directly sa code)

Note: The analytics should be inside the system, not only in Deepnote.

Apply: Add an Analytics page or tab on the admin dashboard. Show them in the React app using the results from your Python analysis.

--- Tag all the reports if the same ---

If many people report the same incident, tag those reports as duplicates and link them together, so responders don't handle it many times.

Apply: The reports table (add a duplicate flag or a "main incident ID"), and an admin action to tag or merge duplicates. You can also suggest a match when the type, place, and time are close. This also keeps your analytics from counting one incident many times.
